

A tutorial on principal component analysis

Rasmus R. Paulsen

DTU Compute

Based on

Jonathan Shlens: A tutorial on Principal Component Analysis (version 3.02
– April 7, 2014)

<http://compute.dtu.dk/courses/02515>

What is your experience with Principal Component Analysis (PCA)

I never heard of PCA before this course

I have seen PCA mentioned before

I have read about PCA but never used it

I have used PCA a few times

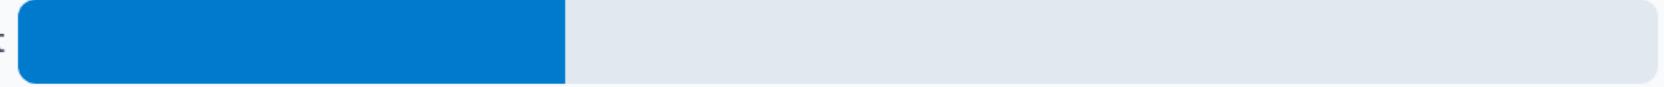

PCA and I are practically best friends

What is your experience with Principal Component Analysis (PCA)

I never heard of PCA before this course  32%

I have seen PCA mentioned before  16%

I have read about PCA but never used it  11%

I have used PCA a few times  32%

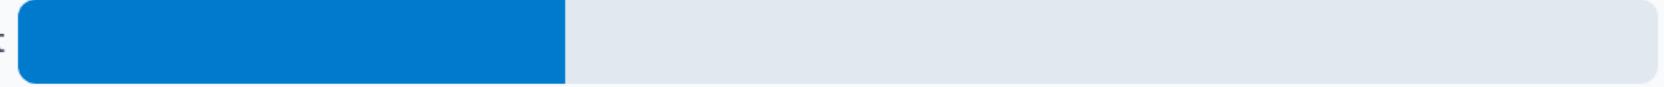

PCA and I are practically best friends  11%

Principal Component Analysis (PCA) learning objectives

- Describe the concept of principal component analysis
- Explain why principal component analysis can be beneficial when there is high data redundancy
- Arrange a set of multivariate measurements into a matrix that is suitable for PCA analysis
- Compute the covariance of two sets of measurements
- Compute the covariance matrix from a set of multivariate measurements
- Compute the principal components of a data set using Eigenvector decomposition
- Describe how much of the total variation in the data set that is explained by each principal component

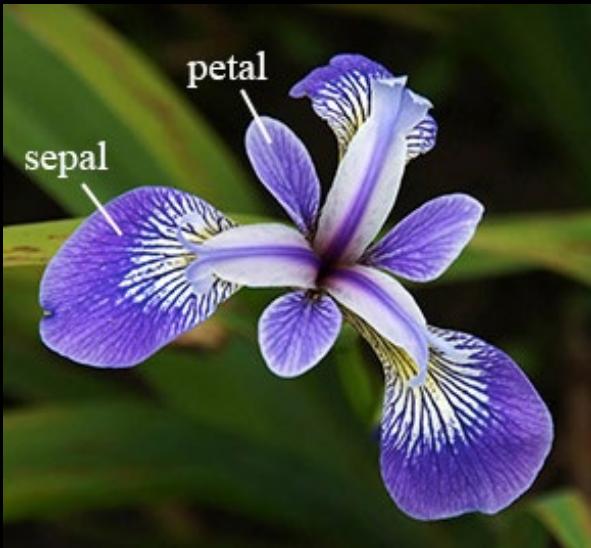

Iris data

The **Iris flower** data

set or Fisher's Iris data set is a data set introduced by Ronald Fisher in his 1936 paper *The use of multiple measurements in taxonomic problems*

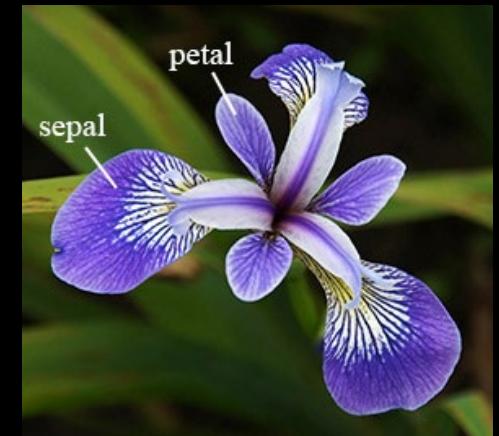

Iris data

- 3 Iris types
 - 50 flowers of each type
- For each flower
 - Sepal length
 - Sepal width
 - Petal length
 - Petal width
- We use one type as example
 - 50 measured flowers

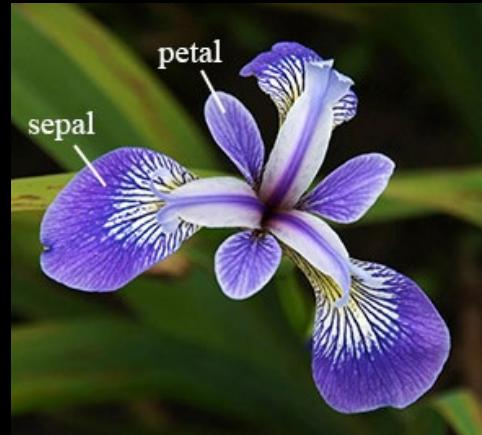

Iris Data Matrix

- One column is one flower
- One row is all measurements of one type

$$\mathbf{X} = \begin{bmatrix} \text{1} & \text{Sepal length}_1 & \dots & \text{Sepal length}_{50} \\ & \text{Sepal width}_1 & \dots & \text{Sepal width}_{50} \\ & \text{Petal length}_1 & \dots & \text{Petal length}_{50} \\ & \text{Petal width}_1 & \dots & \text{Petal width}_{50} \end{bmatrix}$$

What can we use these data for?

- The measurements can be used to:
 - Recognize a species of flowers
 - Classify flowers into groups
 - Describe the characteristics of the flower
 - Quantify growth rates
 - ...
- Do we need all the measurements?
 - Can we *boil down* or *combine* some measurements?
- Are some measurements *redundant*?

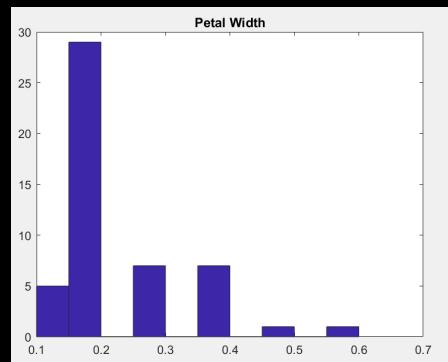

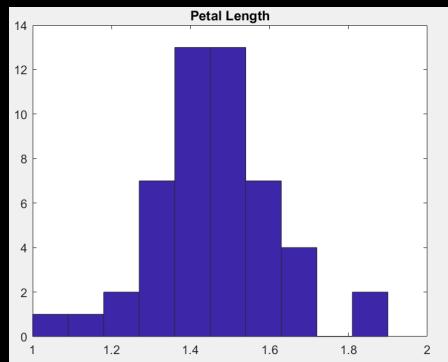

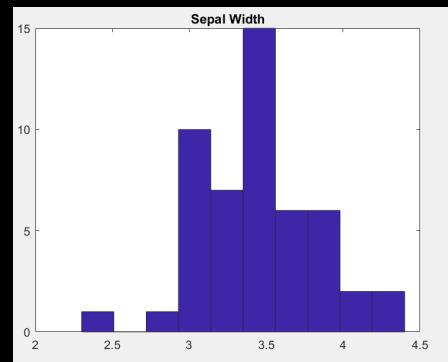

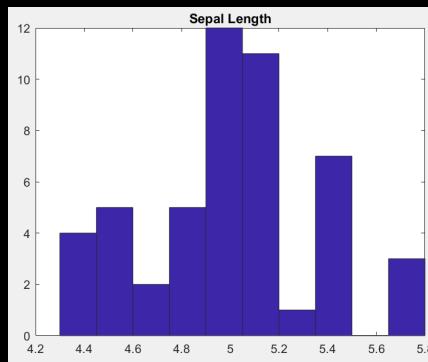

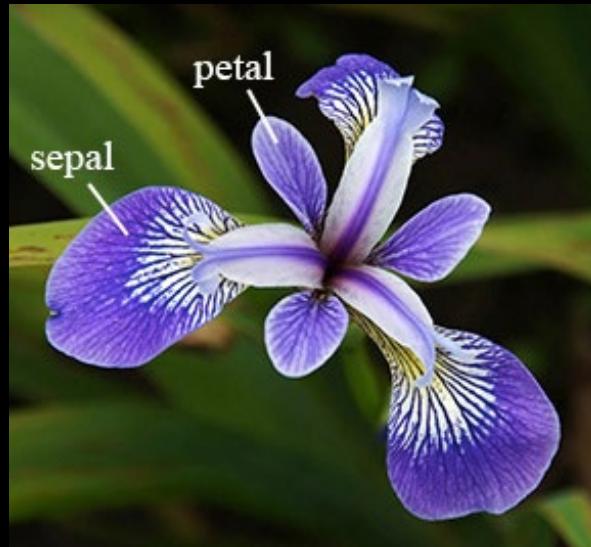

Variance

$$\sigma_{SL}^2 = 0.1242$$

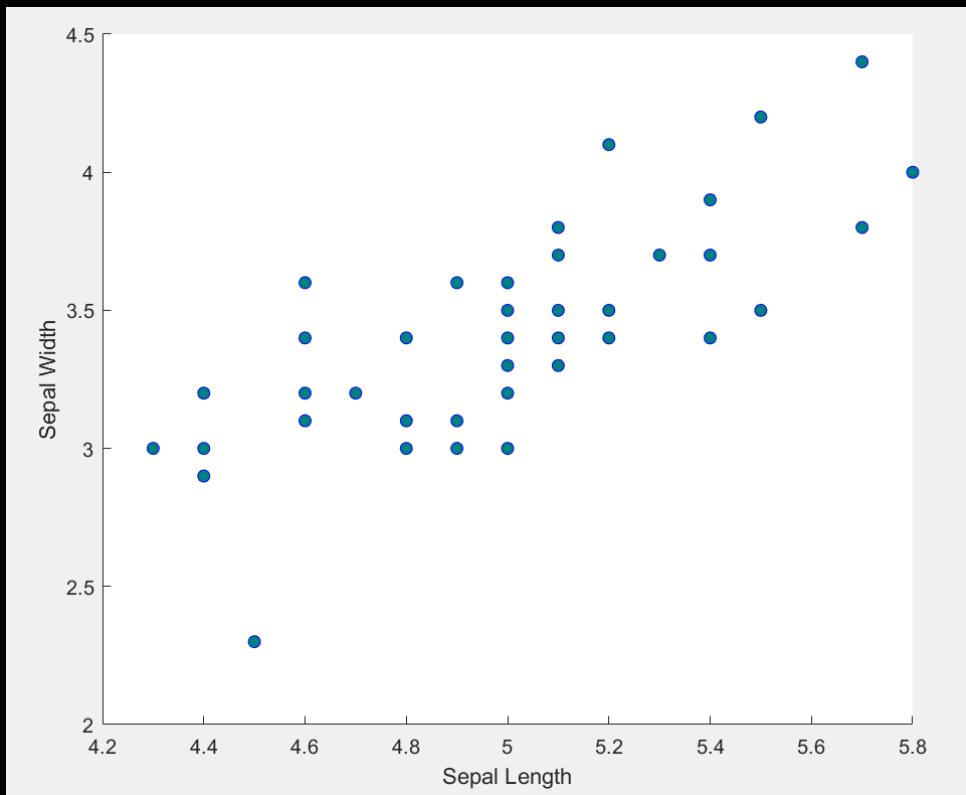

$$\sigma_{SW}^2 = 0.1437$$

$$\sigma_{PL}^2 = 0.0302$$

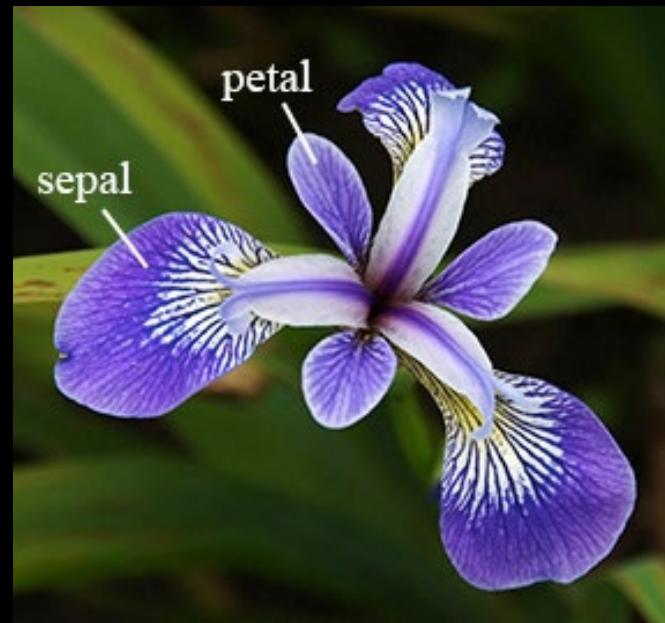

$$\sigma_{PW}^2 = 0.0111$$

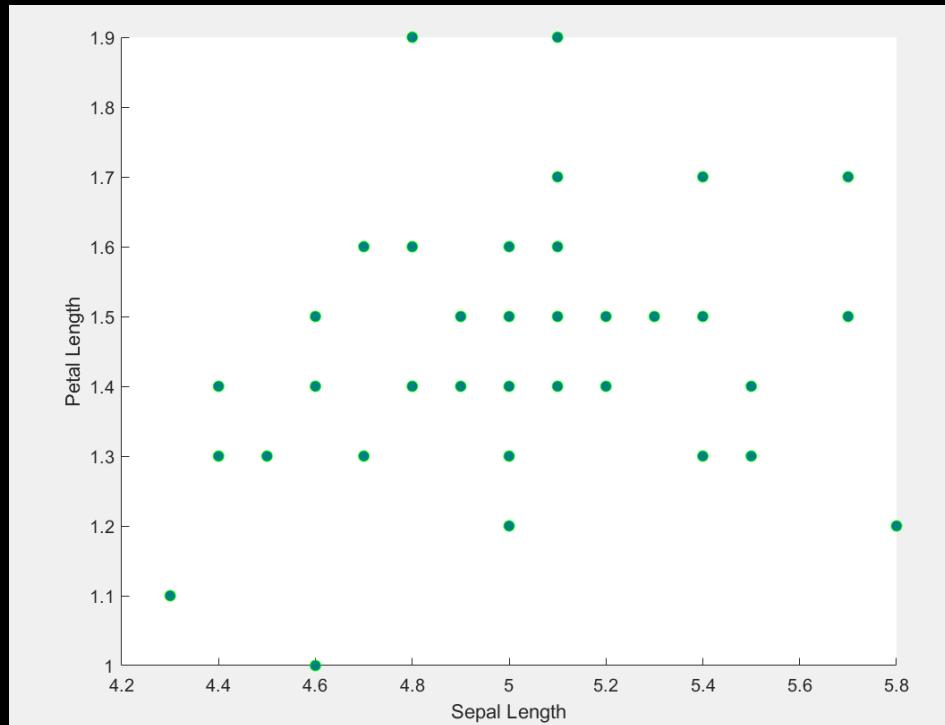

High Redundancy

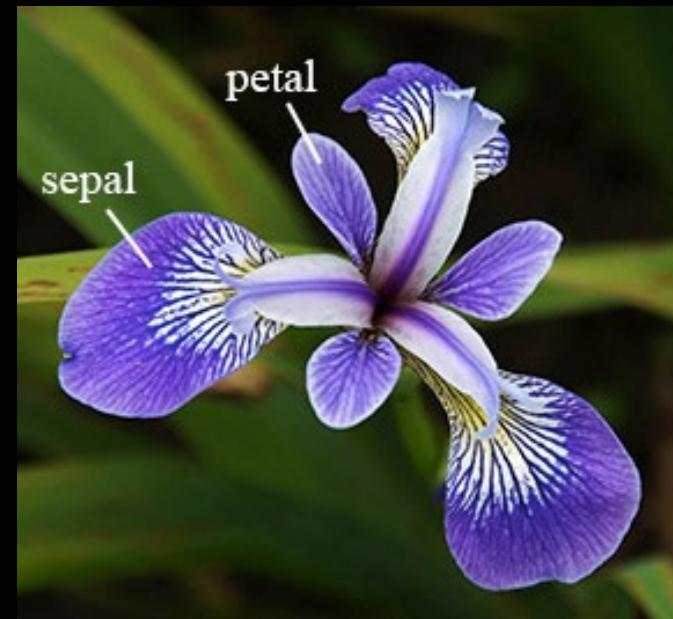

Observation: We can explain quite a lot of the sepal width if we know the sepal lengths

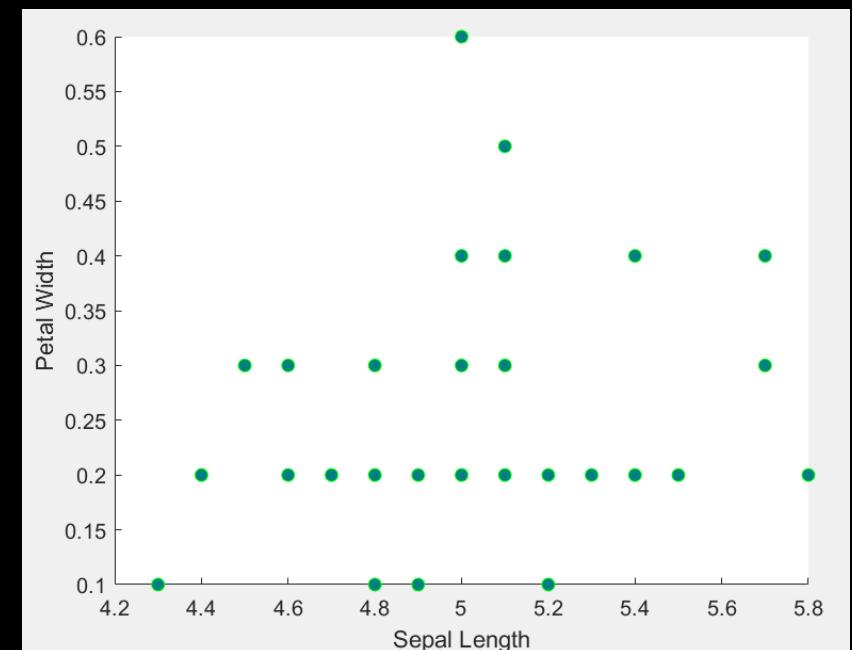

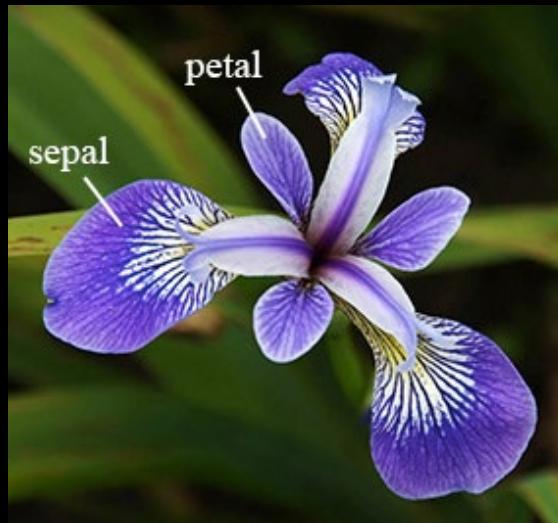

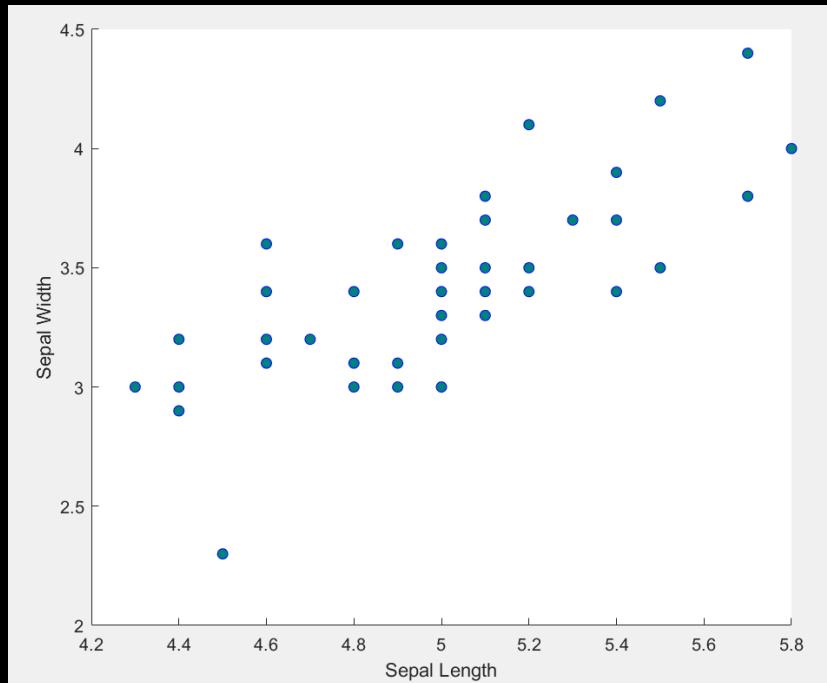

Low Redundancy

Observation: We can **NOT** explain the petal length if we know the sepal lengths

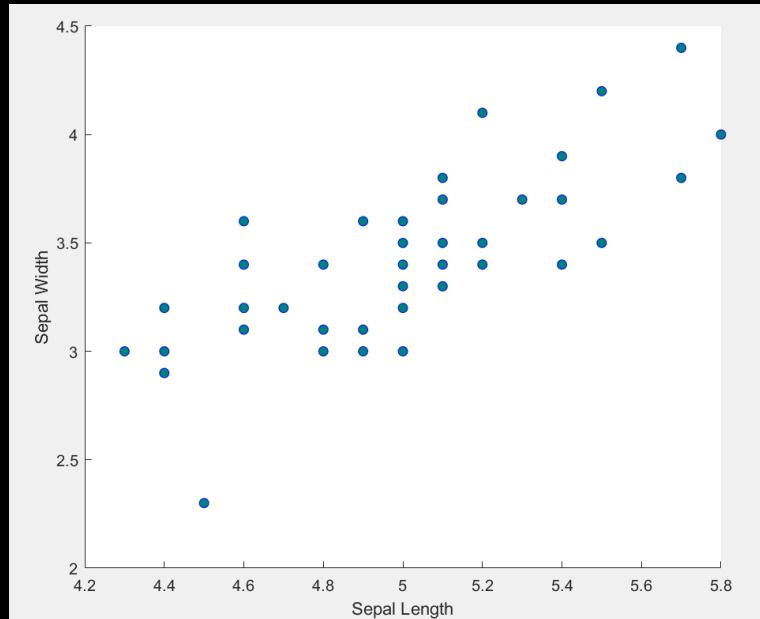

Covariance

Covariance measures the *relationship* between measurements

High Covariance

Sepal length and sepal width

$$a_i = \text{SL} = \{5.1, 4.9 \dots, 5\}$$

$$b_i = \text{SW} = \{3.5, 3, \dots, 3.3\}$$

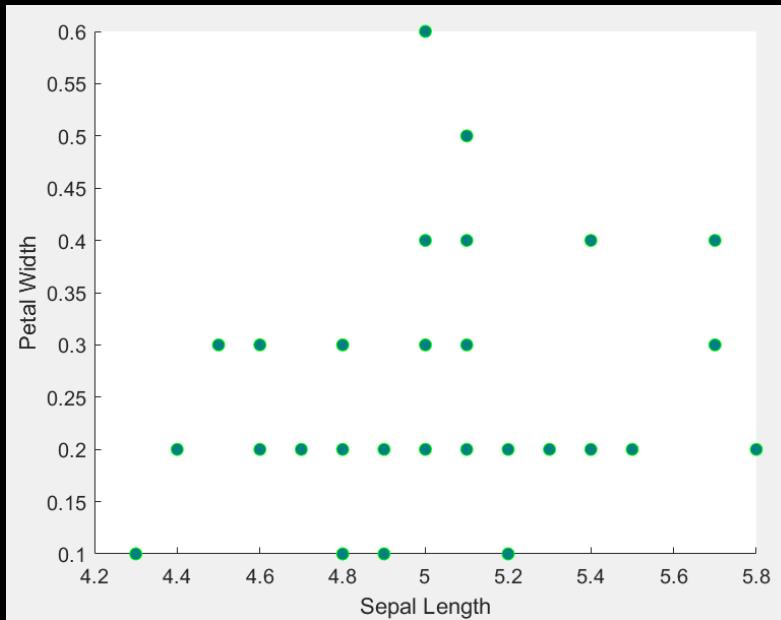

$$\sigma_{\text{SL,SW}}^2 = \frac{1}{n} \sum_i a_i b_i = 17.2578$$

Note that in practice $n-1$ is used instead of n

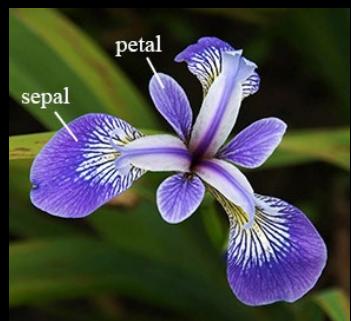

Low covariance

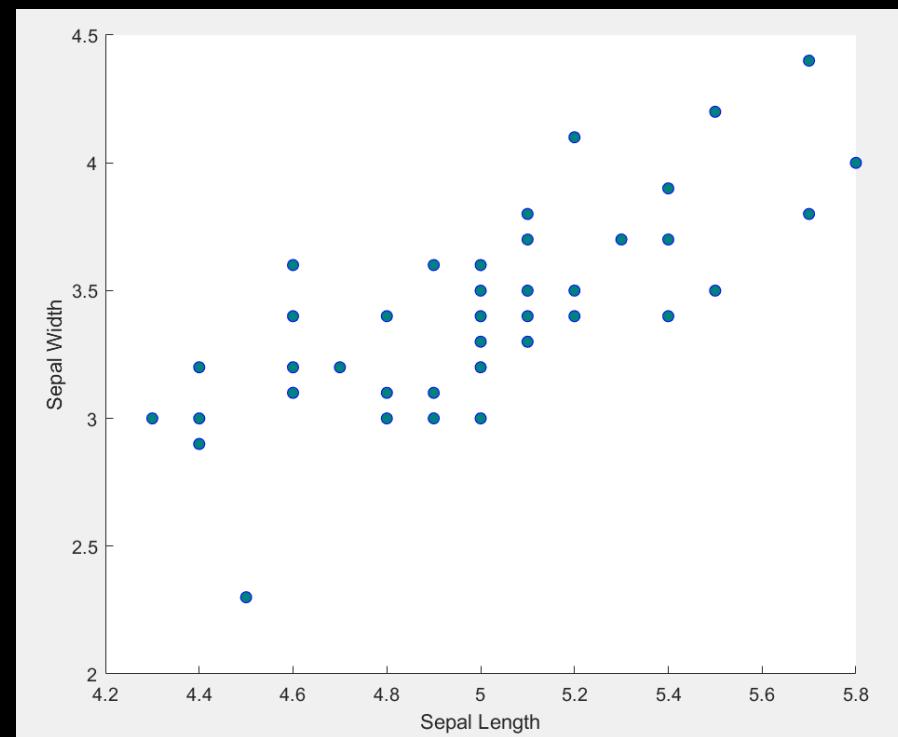

Sepal length and petal width

$$\sigma_{\text{SL}, \text{PW}}^2 = \frac{1}{n} \sum_i a_i b_i = 1.2416$$

Vector notation for covariance

Sepal length and sepal width

$$\mathbf{a} = \mathbf{SL} = [5.1, 4.9 \dots, 5]$$

$$\mathbf{b} = SW = [3.5, 3, \dots, 3.3]$$

$$\sigma_{\text{SL,SW}}^2 = \frac{1}{n} \mathbf{a} \mathbf{b}^T$$

Matrix notation for covariance

$m \times n$ matrix ($m=4$ and $n=50$)

$$\mathbf{X} = \begin{bmatrix} \text{Sepal length}_1 & \dots & \text{Sepal length}_{50} \\ \text{Sepal width}_1 & \dots & \text{Sepal width}_{50} \\ \text{Petal length}_1 & \dots & \text{Petal length}_{50} \\ \text{Petal width}_1 & \dots & \text{Petal width}_{50} \end{bmatrix}$$

$$\mathbf{C}_{\mathbf{X}} \equiv \frac{1}{n} \mathbf{X} \mathbf{X}^T$$

$m \times m$ square matrix
($m=4$)

Note that in practice $n-1$ is used instead of n

Covariance matrix autopsy

$$\mathbf{C}_X \equiv \frac{1}{n} \mathbf{X} \mathbf{X}^T$$

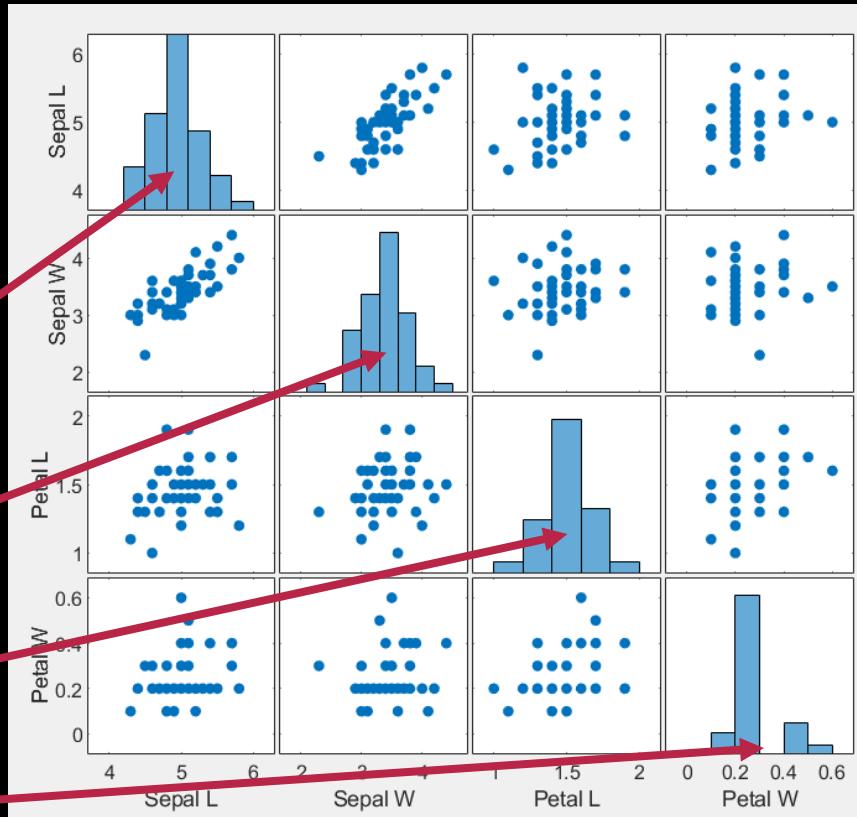

The diagonal elements are the variances

$$\sigma_{SL}^2 = 0.1242$$

$$\sigma_{SW}^2 = 0.1437$$

$$\sigma_{PL}^2 = 0.0302$$

$$\sigma_{PW}^2 = 0.0111$$

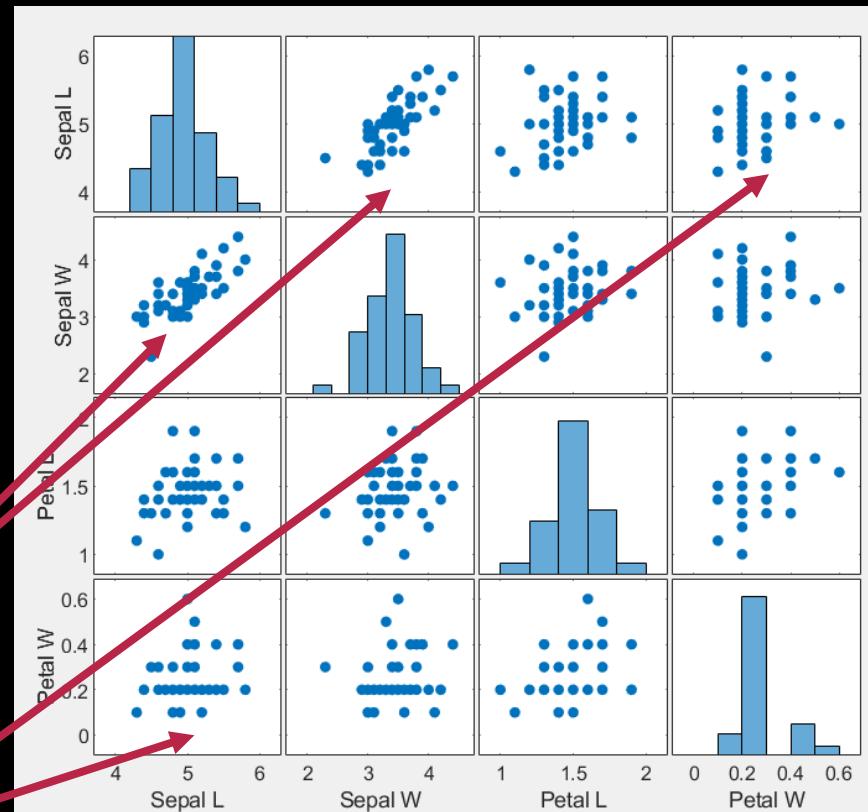

Covariance matrix autopsy II

$$\mathbf{C}_X \equiv \frac{1}{n} \mathbf{X} \mathbf{X}^T$$

The off-diagonal elements are the covariance

$$\sigma_{SL,SW}^2 = \frac{1}{n} \sum_i a_i b_i = 17.2578$$

$$\sigma_{SL,PW}^2 = \frac{1}{n} \sum_i a_i b_i = 1.2416$$

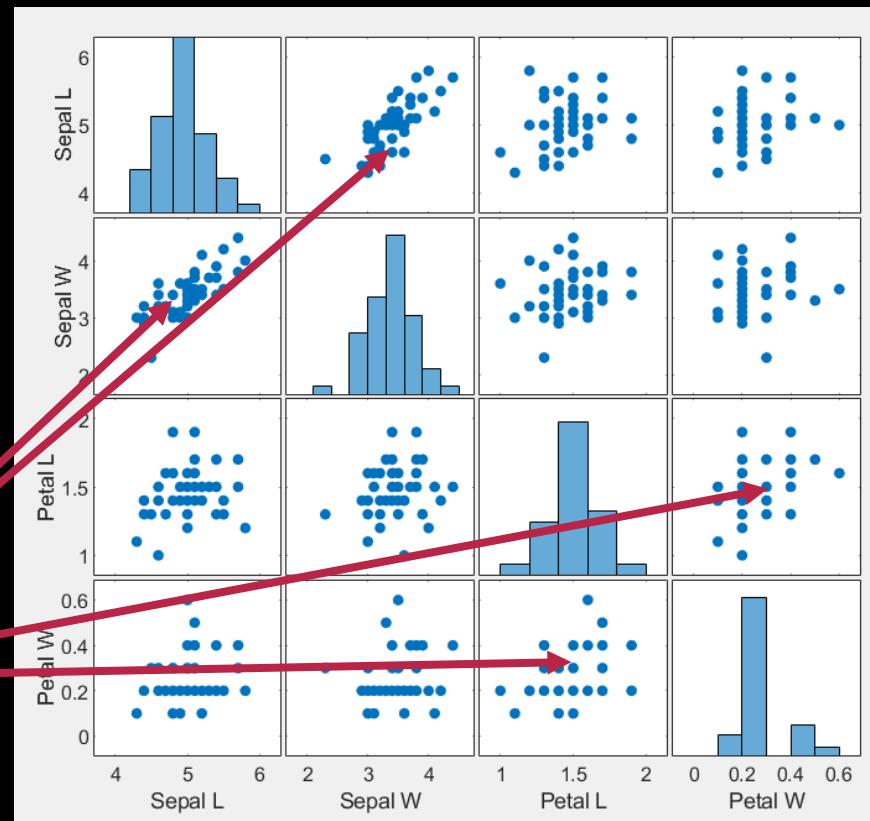

Symmetric!

Covariance matrix autopsy III

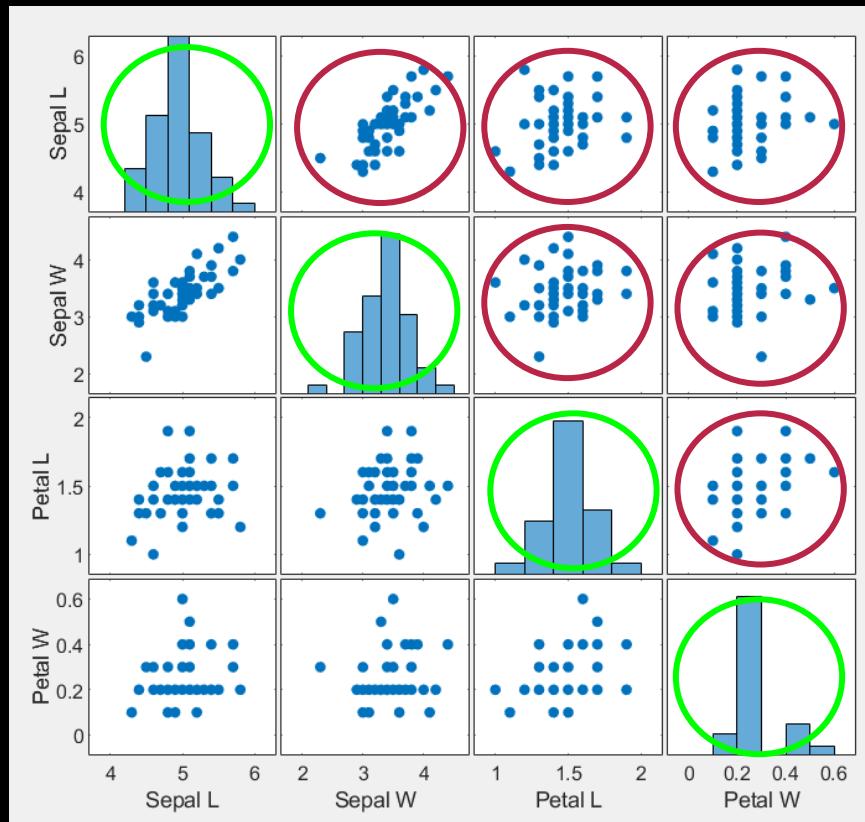

$$C_X \equiv \frac{1}{n} \mathbf{X} \mathbf{X}^T$$

High redundancy

Symmetric!

Goals

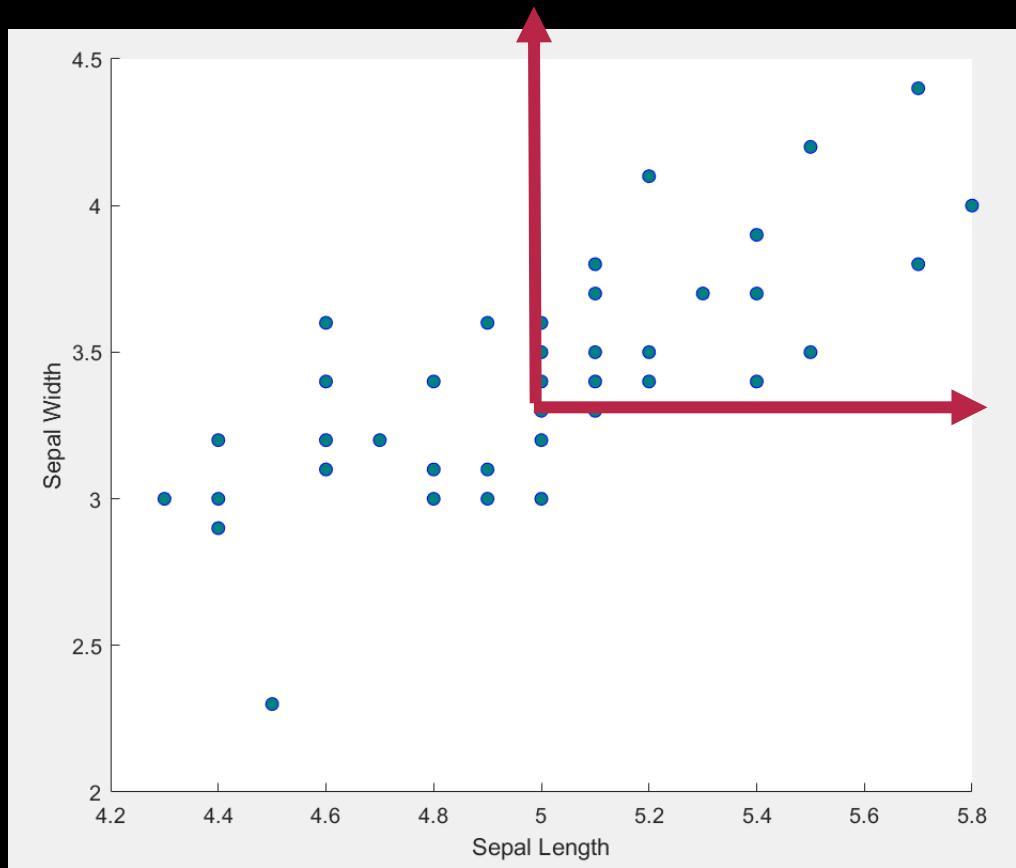

- Minimize redundancy
 - Covariance should be small
- Maximize signal
 - Variance should be large

Signal to noise ratio:

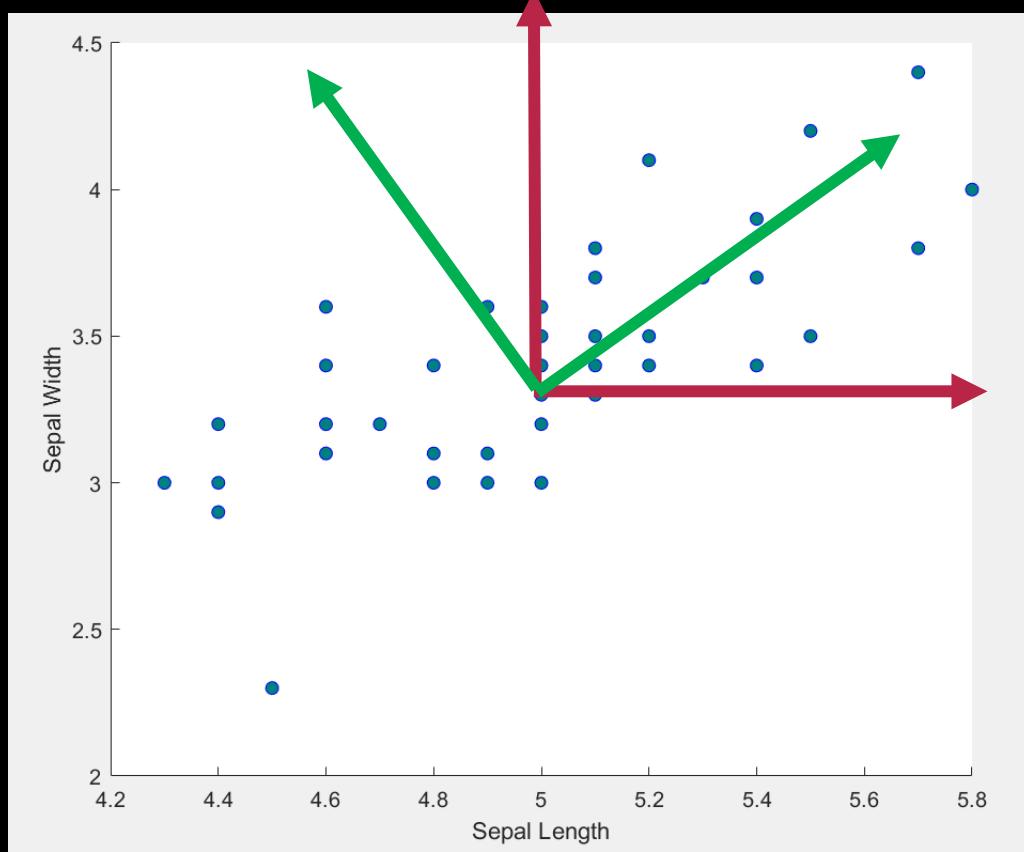

$$\text{SNR} = \frac{\sigma_{\text{signal}}^2}{\sigma_{\text{noise}}^2}$$

Changing basis

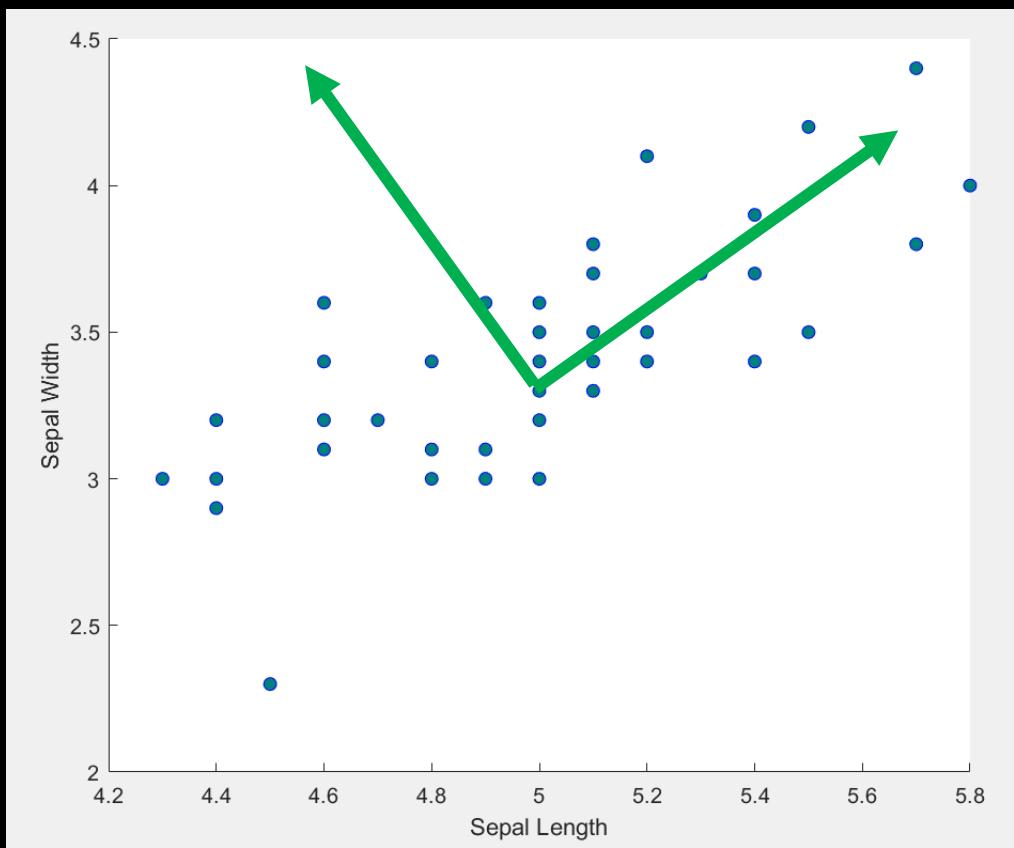

- We start by subtracting the mean
 - Centering data
- Red lines are the default basis

Changing basis

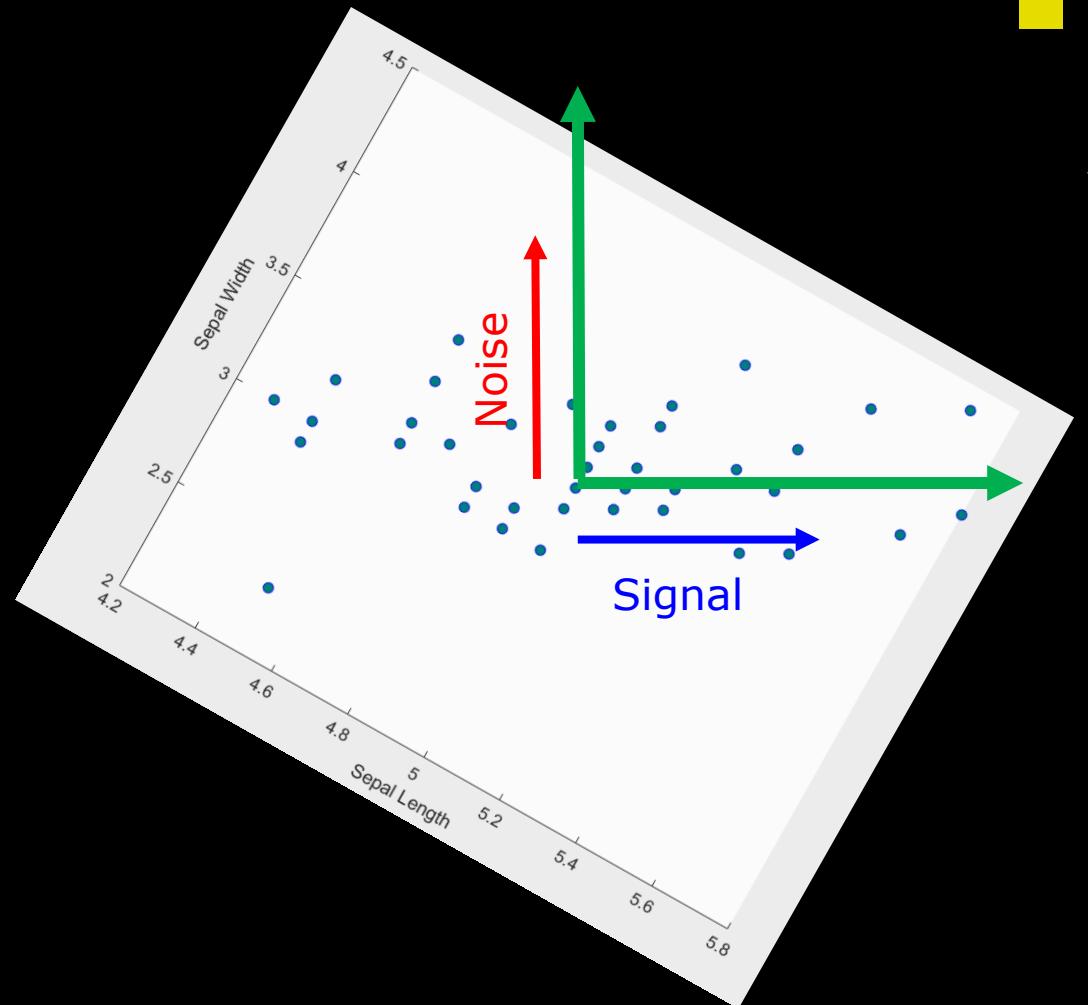

Changing basis

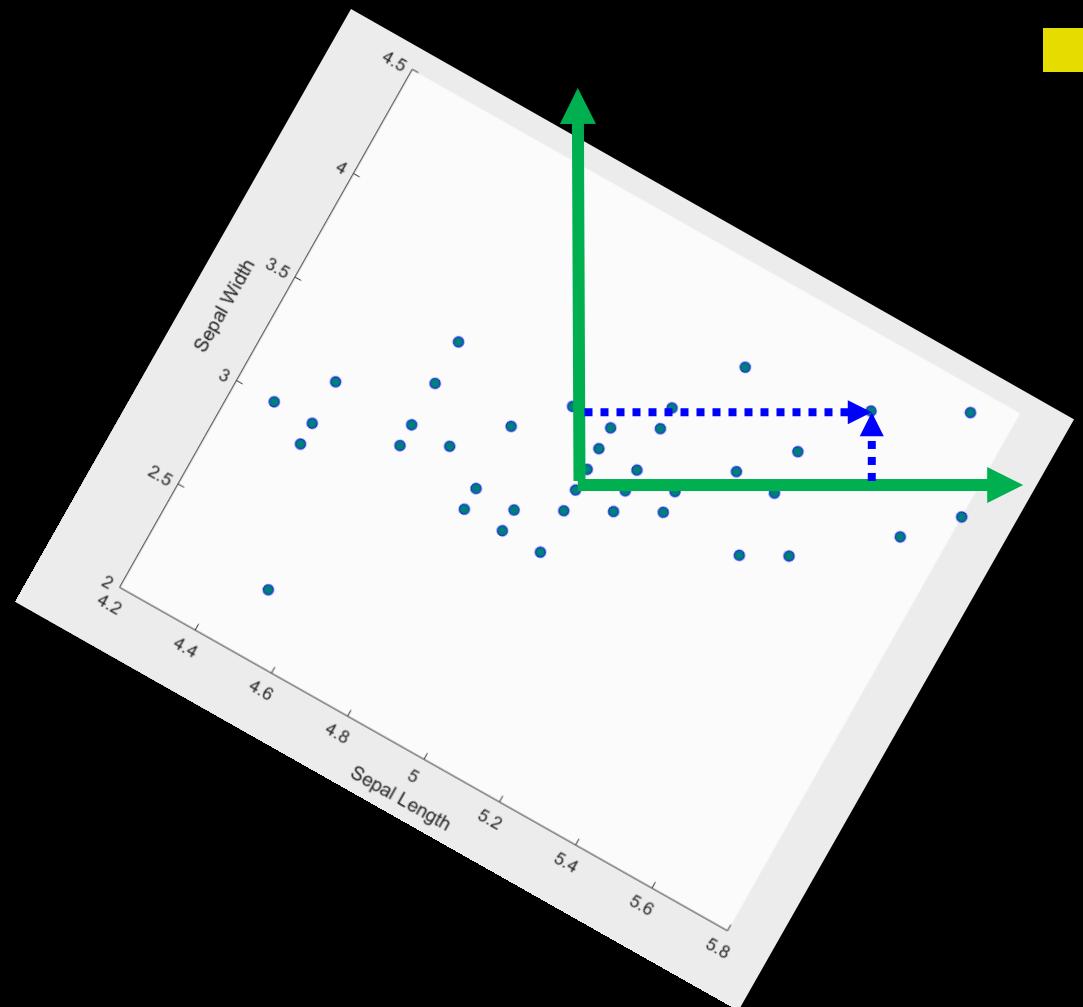

- A new basis that follows the *covariance* in the data

Changing basis

- Lets try to rotate the data – for visualisation

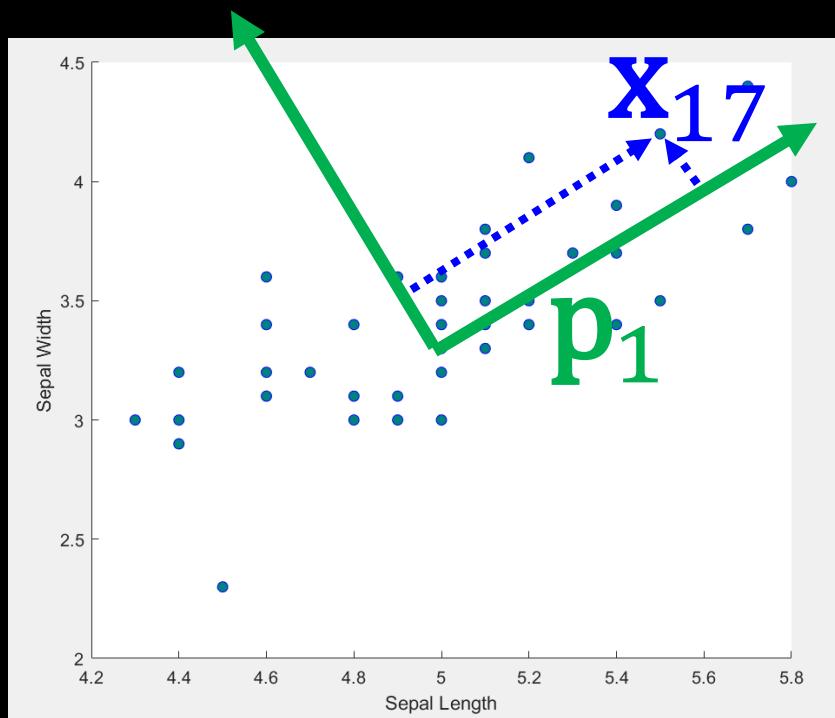

Changing basis

- Finding the measurement values in the new basis

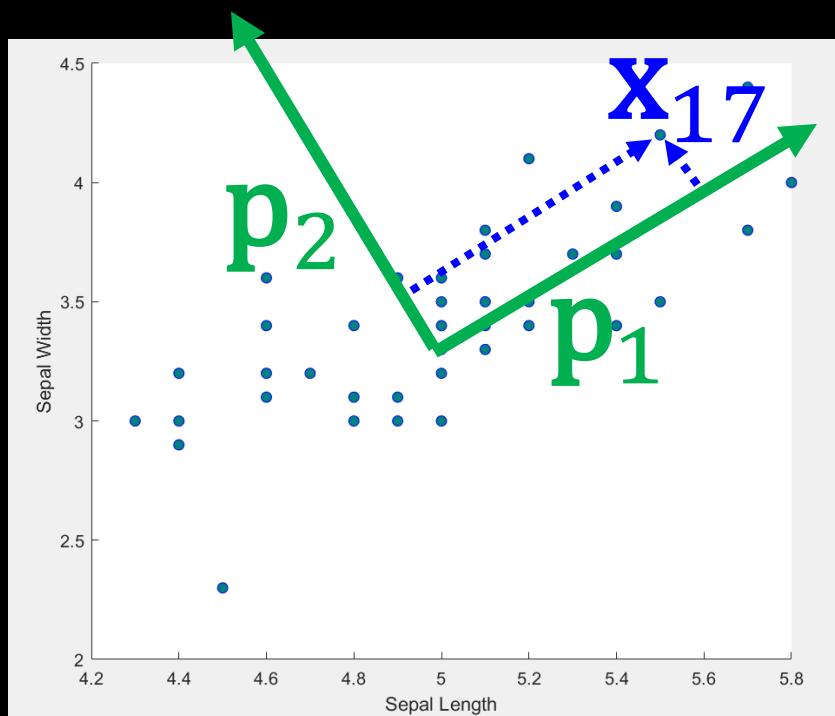

Changing basis

- The dot product projects a point down to a new axis

$$\mathbf{x}_{17,\text{new}} = x_{17} \cdot p_1$$

Changing basis

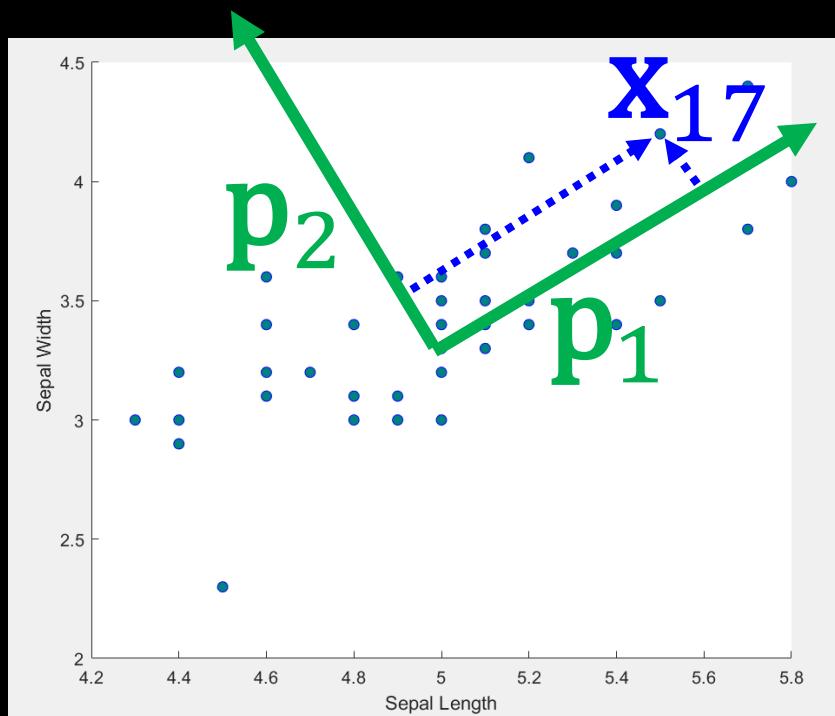

- The dot product projects a point down to a new axis

$$PX = Y$$

- p_1 and p_2 are the rows of P

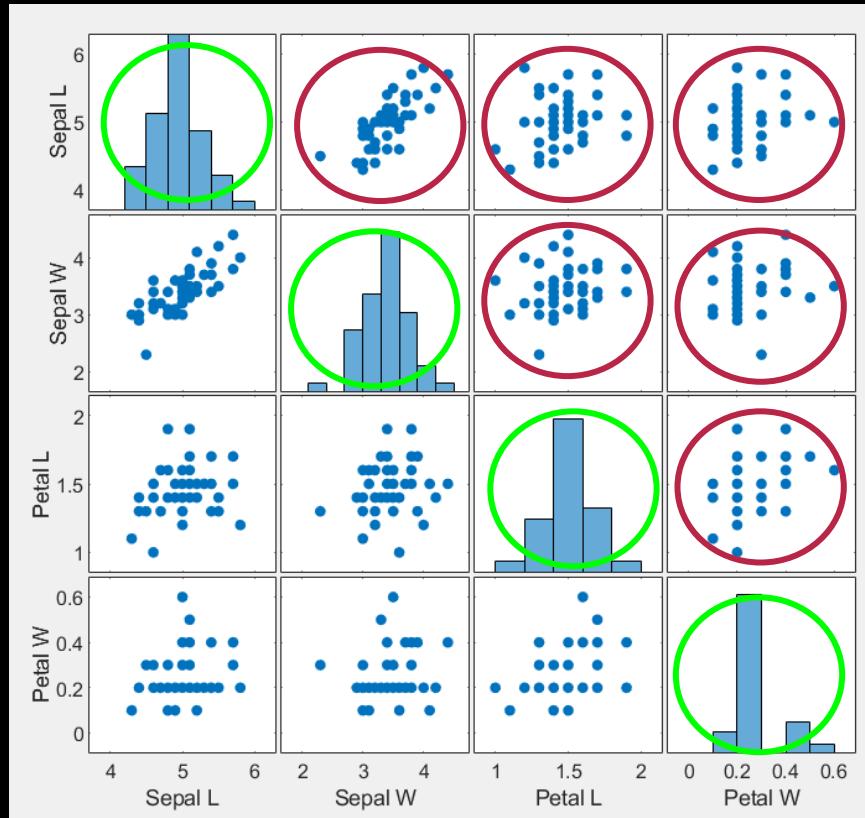

$$\mathbf{X} = \begin{bmatrix} \text{Sepal length}_1 & \dots & \text{Sepal length}_{50} \\ \text{Sepal width}_1 & \dots & \text{Sepal width}_{50} \\ \text{Petal length}_1 & \dots & \text{Petal length}_{50} \\ \text{Petal width}_1 & \dots & \text{Petal width}_{50} \end{bmatrix}$$

Changing basis

- The dot product projects a point down to a new axis $\mathbf{P}\mathbf{X} = \mathbf{Y}$
- Here \mathbf{Y} contains the new coordinates/measurements per sample

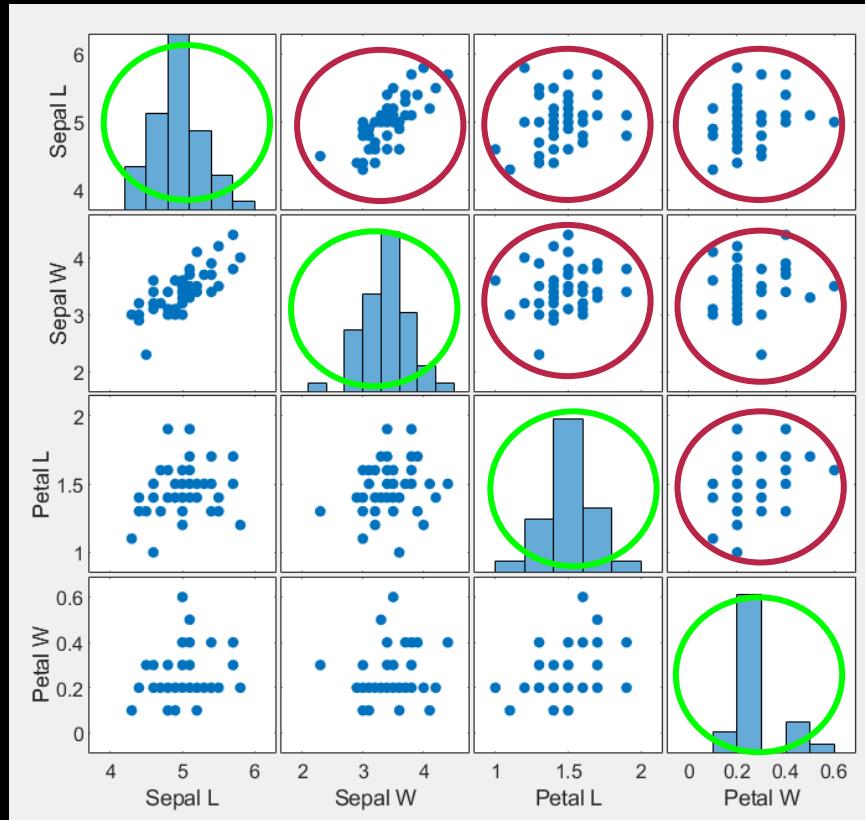

Goals

- Minimize redundancy
 - Covariance should be small
- Maximize signal
 - Variance should be large
- Transform our data
 - Rotating and scaling the basis
- $\mathbf{Y} = \mathbf{P}\mathbf{X}$
- So it will have

$$\mathbf{C}_Y \equiv \frac{1}{n} \mathbf{Y} \mathbf{Y}^T$$

Goals

- The covariance matrix

$$\mathbf{C}_Y \equiv \frac{1}{n} \mathbf{Y} \mathbf{Y}^T$$

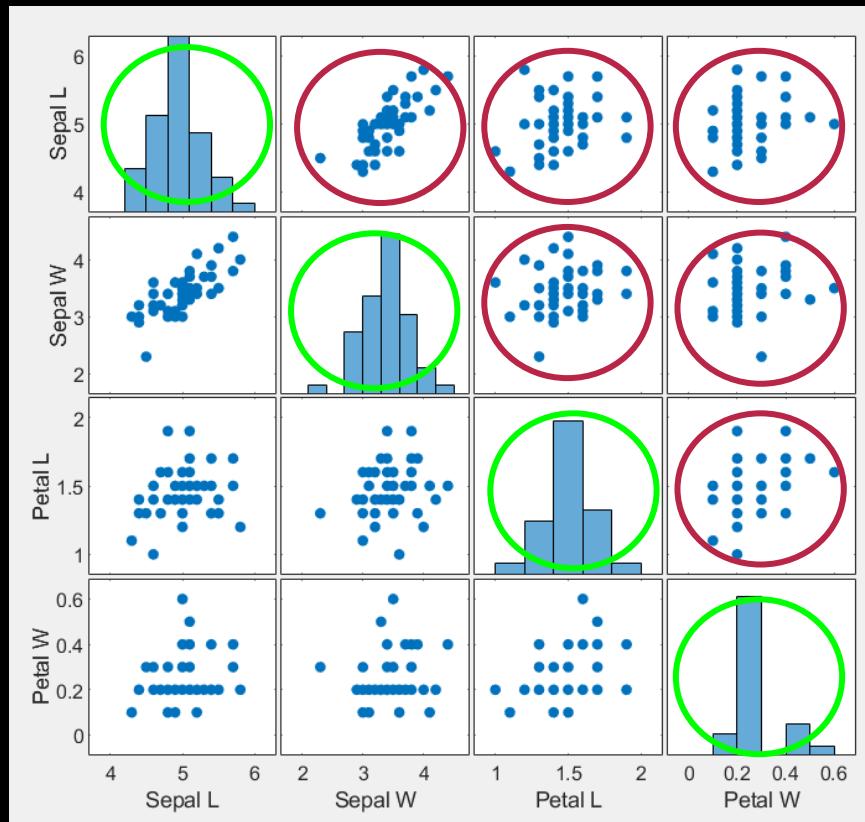

- Should be *as diagonal as possible*

- We do this by

$$\mathbf{Y} = \mathbf{P} \mathbf{X}$$

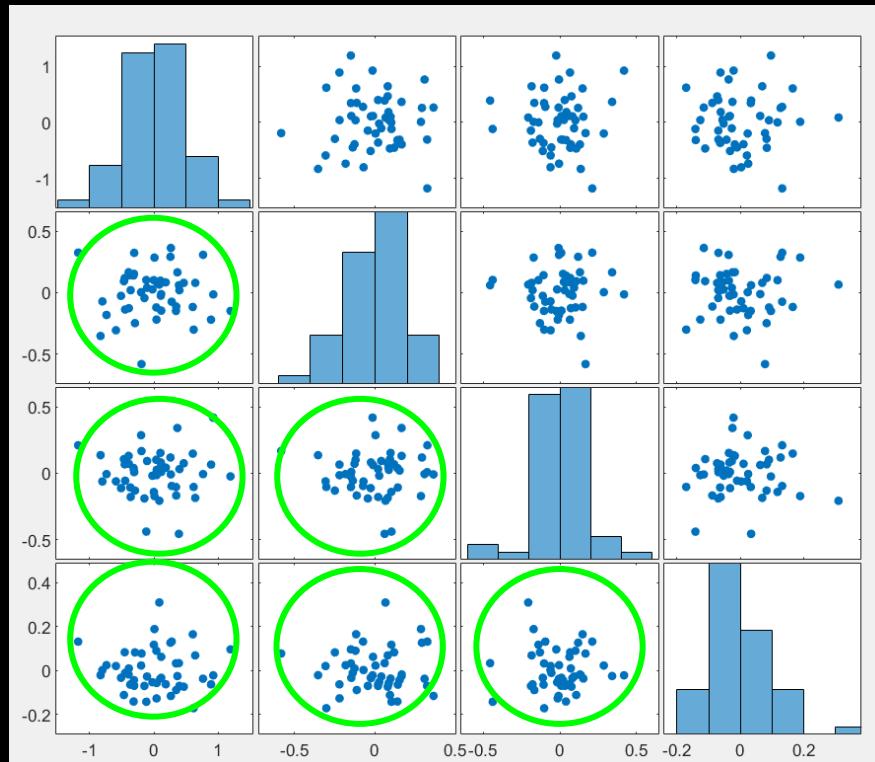

- Where **P** are the principal components

Computing the principal components

- The Principal Components of \mathbf{X} are the **eigenvectors** of $\mathbf{C}_\mathbf{X} \equiv \frac{1}{n} \mathbf{X} \mathbf{X}^T$
- The i 'th diagonal value of \mathbf{C}_Y is the variance along principal component number i

New covariance matrix for Iris data

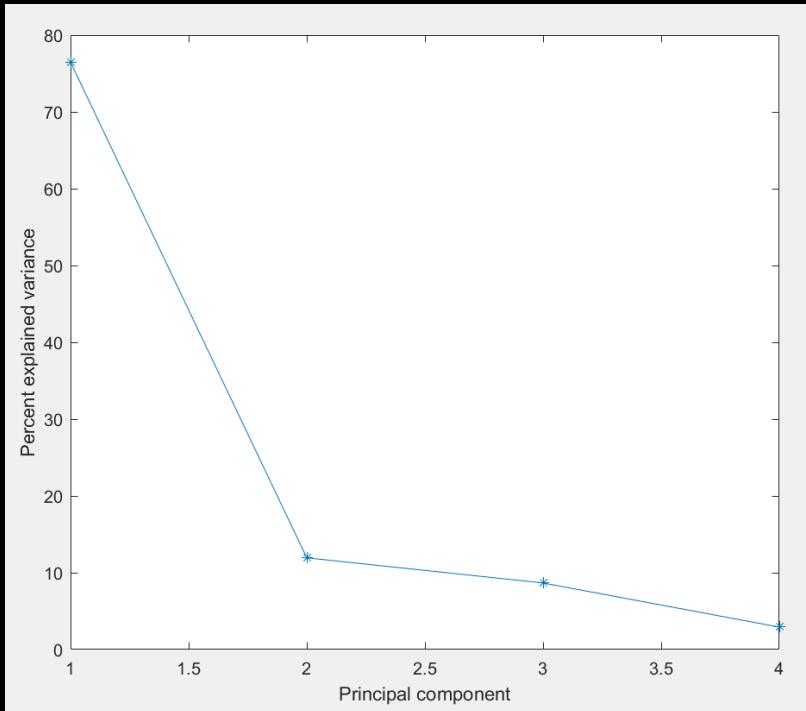

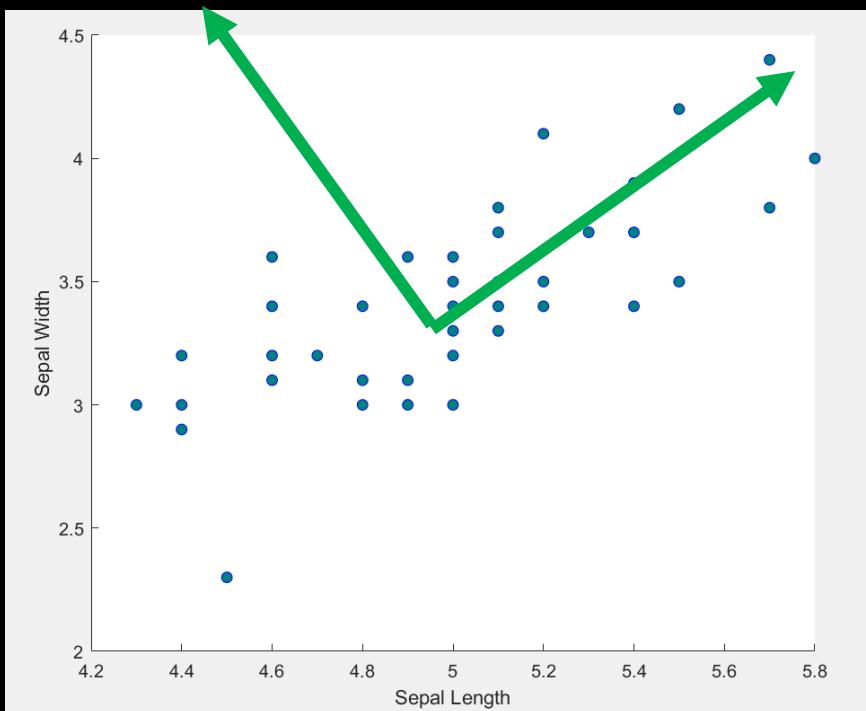

- The principal component are found and

$$\mathbf{Y} = \mathbf{P}\mathbf{X}$$

- With the covariance matrix

$$\mathbf{C}_{\mathbf{Y}} \equiv \frac{1}{n} \mathbf{Y} \mathbf{Y}^T$$

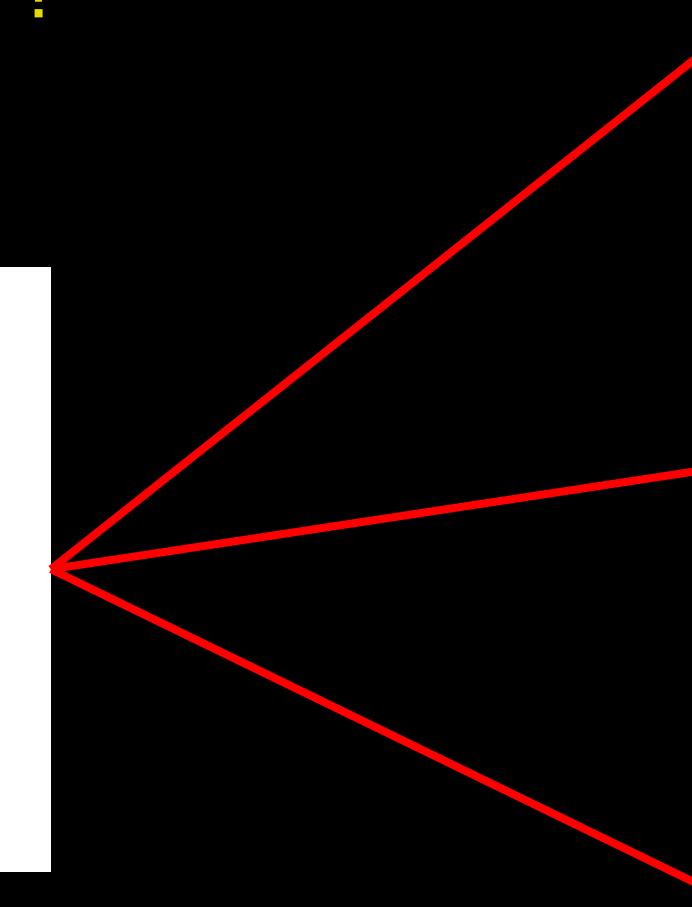

Explained variance

One component explains 75% of the total variation – so for each flower we can have one number that explains 75% percent of the 4 measurements!

What can we use it for?

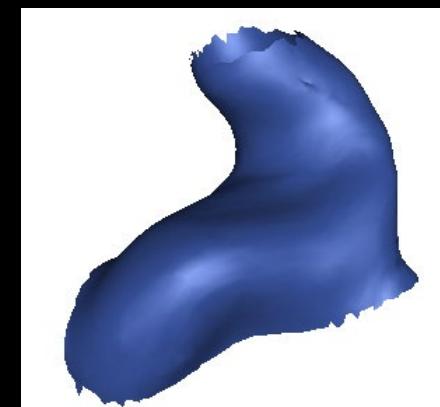

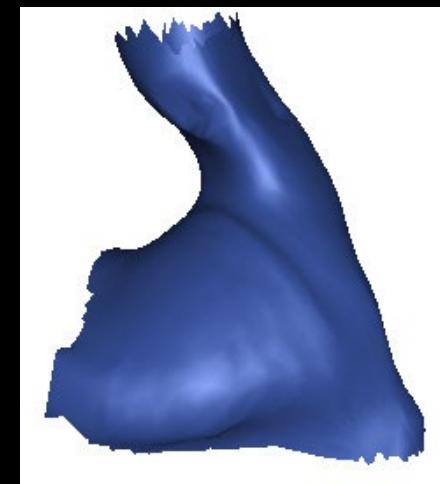

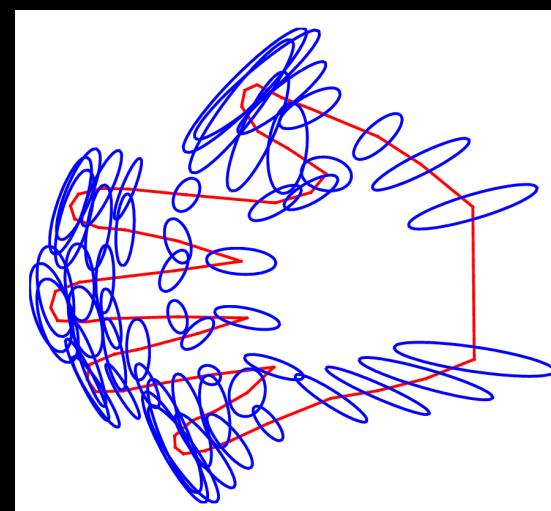

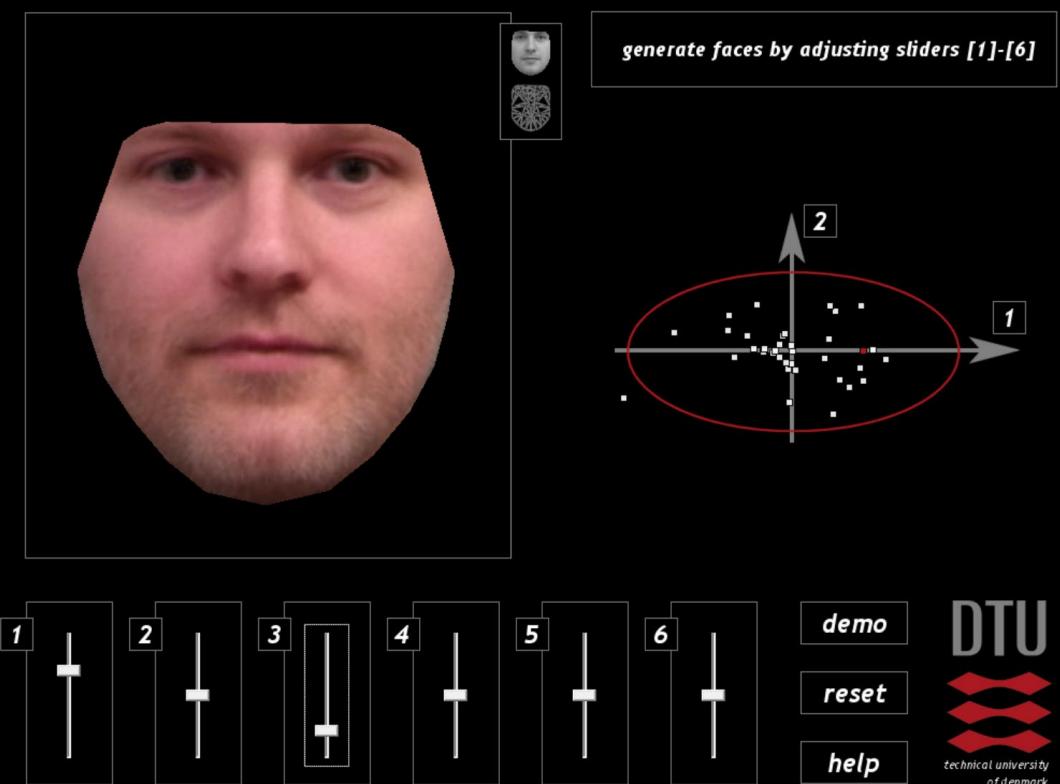

■ Classification

Based on one value instead of 4

What can we use it for?

- Many more examples in the course

Final note – practical estimation of covariance matrix

$$\mathbf{C}_\mathbf{X} \equiv \frac{1}{n} \mathbf{X} \mathbf{X}^T$$

In practice $n-1$ is used instead of n for exercises and in the exam.

$$\mathbf{C}_\mathbf{X} \equiv \frac{1}{n-1} \mathbf{X} \mathbf{X}^T$$
